## Exercise 5: Optimization Landscape of Neural Networks

Lecturer: Aurelien Lucchi

## Problem 1 (Matrix Completion):

We consider the problem of matrix sensing where we have a model parametrized by  $\mathbf{W} \in \mathbb{R}^{d \times d}$ . We observe a set of linear measurements of the form  $\langle \mathbf{W}, \mathbf{A}_n \rangle_F$  where  $[\mathbf{A}_n]_{ij} \sim \mathcal{N}(0,1)$ . We will further assume that the data is labeled by a matrix sensing model parameterized by  $\mathbf{W}^* \in \mathbb{R}^{d \times d}$  (this is sometimes called "planted model" in the literature).

We will study the dynamics of this model trained with gradient flow on a squared loss. As we will soon see, this setting is related to the problem of training a deep linear network. In order to simulate depth, we will consider the matrix  $\mathbf{W}$  as the product of a set of square matrices  $\mathbf{W}_i \in \mathbb{R}^{d \times d}$ , i.e.  $\mathbf{W} = \mathbf{W}_L \dots \mathbf{W}_1$ .

The objective function is given by

$$\mathcal{L}(\mathbf{W}) = \frac{1}{2L} \mathbb{E}_{\mathbf{A}} \langle \mathbf{W} - \mathbf{W}^*, \mathbf{A} \rangle_F^2 = \frac{1}{2L} \| \mathbf{W}_L \dots \mathbf{W}_1 - \mathbf{W}^* \|_F^2.$$

We will use gradient flow to optimize the parameters and denote by  $\mathbf{W}_k(t)$  the matrices  $\mathbf{W}_k$  at time t.

a) Denote  $\mathbf{W}_{j:k}^{\top} = \prod_{i=j}^{k} \mathbf{W}_{i}^{\top} = \mathbf{W}_{j}^{\top} \mathbf{W}_{j+1}^{\top} \cdots \mathbf{W}_{k}^{\top}$ . The partial gradient of  $\mathcal{L}$  with respect to  $\mathbf{W}_{k}$  (where  $k = 1, \dots, L$ ) is

$$\frac{\partial \mathcal{L}(\mathbf{W})}{\partial \mathbf{W}_k} = \frac{1}{L} \mathbf{W}_{k+1:L}^{\top} (\mathbf{W} - \mathbf{W}^*) \mathbf{W}_{1:k-1}^{\top}.$$

What is the gradient flow equation for the matrix  $\mathbf{W}_k$ ?

b) Prove that for all  $t \geq 0$  and k = 1, ..., L - 1:

$$\mathbf{W}_{k+1}^{\mathsf{T}}(t)\dot{\mathbf{W}}_{k+1}(t) = \dot{\mathbf{W}}_{k}(t)\mathbf{W}_{k}^{\mathsf{T}}(t). \tag{1}$$

And hence

$$\mathbf{W}_{k+1}^{\mathsf{T}}(t)\mathbf{W}_{k+1}(t) = \mathbf{W}_{k}(t)\mathbf{W}_{k}^{\mathsf{T}}(t). \tag{2}$$

c) For any  $t \ge 0$  and k = 1, ..., L, assume the singular values of  $\mathbf{W}_k$  are all distinct and indexed in strictly decreasing order:  $\sigma_1 > ... > \sigma_d > 0$ , and let  $\mathbf{W}_k = \mathbf{U}_k \mathbf{\Sigma}_k \mathbf{V}_k^{\top}$  be its (unique) singular value decomposition (SVD). Show that

$$\Sigma_{k+1} = \Sigma_k, \qquad \mathbf{U}_k = \mathbf{V}_{k+1},$$

for any  $t \geq 0$  and k = 1, ..., L.

d) Denote  $\Sigma = \Sigma_1 = \cdots = \Sigma_L \in \mathbb{R}^{d \times d}$ . Now prove that the gradient flow equation can be written as:

$$\dot{\mathbf{W}}_k = \frac{1}{L} \mathbf{V}_{k+1} \mathbf{\Sigma}^{L-k} \mathbf{U}_L^{\top} \left( \mathbf{W}^* - \mathbf{U}_L \mathbf{\Sigma}^L \mathbf{V}_1^{\top} \right) \mathbf{V}_1 \mathbf{\Sigma}^{k-1} \mathbf{V}_{k-1}^{\top},$$

for all k = 1, ..., L.

e) By the product rule  $\dot{\mathbf{W}} = \sum_{k=1}^{L} \mathbf{W}_{L:k+1} \dot{\mathbf{W}}_k \mathbf{W}_{k-1:1}$ , show that

$$\dot{\mathbf{W}} = rac{1}{L} \sum_{k=1}^{L} \mathbf{U}_L \mathbf{\Sigma}^{2L-2k} \mathbf{U}_L^{ op} \left( \mathbf{W}^* - \mathbf{U}_L \mathbf{\Sigma}^L \mathbf{V}_1^{ op} \right) \mathbf{V}_1 \mathbf{\Sigma}^{2k-2} \mathbf{V}_1^{ op}.$$

f) Alternatively, show that the gradient flow can be expressed solely in terms of W:

$$\dot{\mathbf{W}} = \frac{1}{L} \sum_{k=1}^{L} \left[ \mathbf{W} \mathbf{W}^{\top} \right]^{\frac{L-k}{L}} \left( \mathbf{W}^* - \mathbf{W} \right) \left[ \mathbf{W}^{\top} \mathbf{W} \right]^{\frac{k-1}{L}}.$$

1

## Problem 2 (Network near initialization):

Given an input vector  $\mathbf{x} \in \mathbb{R}^d$ , consider a shallow neural network defined by

$$f(\mathbf{W}) := \sum_{j=1}^{m} a_j \sigma(\mathbf{w}_j^{\top} \mathbf{x}), \qquad \mathbf{W} := \begin{bmatrix} \leftarrow \mathbf{w}_1^{\top} \to \\ \vdots \\ \leftarrow \mathbf{w}_m^{\top} \to \end{bmatrix} \in \mathbb{R}^{m \times d},$$

where  $\sigma$  is an activation function,  $\mathbf{a} \in \mathbb{R}^m$  is a fixed (not trainable) vector of weights initialized such that  $a_j \stackrel{\text{i.i.d.}}{\sim} \text{Unif}\left(\pm \frac{1}{\sqrt{m}}\right)^{-1}$ , and  $\mathbf{W} \in \mathbb{R}^{m \times d}$  are trainable weights.

We will consider the linearization of the function f around some initial weights  $\mathbf{W}_0$  defined by

$$f_0(\mathbf{W}) = f(\mathbf{W}_0) + \langle \nabla f(\mathbf{W}_0), \mathbf{W} - \mathbf{W}_0 \rangle_F, \qquad (3)$$

where  $\langle \mathbf{A}, \mathbf{B} \rangle_F = \operatorname{tr}(\mathbf{A}^\top \mathbf{B})$  is the Frobenius inner product.

a) Show that

$$\nabla f(\mathbf{W}) = \mathbf{Dax}^{\top}, \text{ where } \mathbf{D} = \operatorname{diag}(\sigma'(\mathbf{w}_i^{\top}\mathbf{x})) = \begin{pmatrix} \sigma'(\mathbf{w}_1^{\top}\mathbf{x}) & & & \\ & \sigma'(\mathbf{w}_2^{\top}\mathbf{x}) & & \\ & & \cdots & \\ & & \sigma'(\mathbf{w}_m^{\top}\mathbf{x}) \end{pmatrix}.$$

b) Show that

$$\langle \nabla f(\mathbf{W}_0), \mathbf{W} - \mathbf{W}_0 \rangle_F = \sum_{j=1}^m a_j \sigma'(\mathbf{w}_{0,j}^\top \mathbf{x}) (\mathbf{w}_j - \mathbf{w}_{0,j})^\top \mathbf{x},$$

where 
$$\mathbf{W}_0 = \begin{bmatrix} \leftarrow \mathbf{w}_{0,1}^\top \to \\ \vdots \\ \leftarrow \mathbf{w}_{0,m}^\top \to \end{bmatrix}$$
 denotes the weight at initialization.

c) Now assume the activation function  $\sigma$  is  $\beta$ -smooth, which satisfies:

$$|\sigma(r) - \sigma(s) - \sigma'(s)(r-s)| \le \frac{\beta(r-s)^2}{2}$$

for all  $r, s \in \mathbb{R}$ . Show that for any  $\mathbf{W} \in \mathbb{R}^{m \times d}$ ,

$$|f(\mathbf{W}) - f_0(\mathbf{W})| \le \frac{\beta}{2\sqrt{m}} \|\mathbf{W} - \mathbf{W}_0\|_F^2 \|\mathbf{x}\|^2.$$

d) What do you conclude about the role of over-parametrization?

<sup>&</sup>lt;sup>1</sup>Equivalently, one can define  $f(\mathbf{W}) := \frac{1}{\sqrt{m}} \sum_{j=1}^{m} a_j \sigma(\mathbf{w}_j^{\top} \mathbf{x})$  with  $a_j \stackrel{\text{i.i.d.}}{\sim} \text{Unif}(\pm 1)$ .
